ARTESIAN WATER FROM GLACIAL DRIFT NEAR LEHR  
LOGAN AND McINTOSH COUNTIES, NORTH DAKOTA

By  
D. G. Adolphson

Introduction

As a part of the cooperative ground-water investigations program, the North Dakota State Water Conservation Commission, the North Dakota Geological Survey, and the United States Geological Survey make studies of the ground-water resources available for municipal use in various parts of North Dakota. Investigations are made of small areas surrounding towns which have requested aid from the North Dakota State Water Conservation Commission or the State Geologist. When adequate funds become available, more complete investigations will be made of larger areas, such as counties. Reports on these larger areas will include the results of the small municipal water-supply studies.

The field work for this investigation was done in 1956 and data from the test drilling and the analysis of a quality-of-water sample were released to the North Dakota State Water Conservation Commission at that time. The plan at that time was to publish the data with results from an areal ground-water investigation of a larger region. However, as a more comprehensive regional study has not been initiated, this report was prepared in 1960. The field work consisted of test drilling with a rig owned by the State Water Conservation Commission. A total of 17 test holes were drilled to depths ranging from 100 to 450 feet and averaging 175 feet. Samples of the formations were taken from each 5-foot interval. A sample of ground water was obtained from one test hole, and a chemical analysis was made by the North Dakota State Laboratories Department.

### Location and Extent of Area

Lehr, which has a population of 381 (1960 census), is at the northern edge of McIntosh and the southern edge of Logan Counties in south-central North Dakota. It is served by the Minneapolis, St. Paul Sault Ste. Marie Railroad and State Highways 30 and 13. Approximately 16 square miles, parts of T. 133 N., Rs. 69 and 70 W., and T. 132 N., Rs. 69 and 70 W., are included in the area described in this report.

The area (fig. 1) is in the glaciated part of the Missouri Plateau physiographic province of Simpson (1929, p. 10-11), which consists of a broad belt of morainic ridges and hills (sometimes referred to as the Altamont Moraine) formed by one of the advances of the Wisconsin ice sheet in the Pleistocene Epoch. This belt of moraines, which is characterized by numerous undrained depressions, trends southeastward across North Dakota. The undrained depressions in the Lehr area are occupied by swamps, but after heavy precipitation these may become intermittent lakes or ponds. The average annual precipitation in the Lehr area is about  $16\frac{1}{2}$  inches.

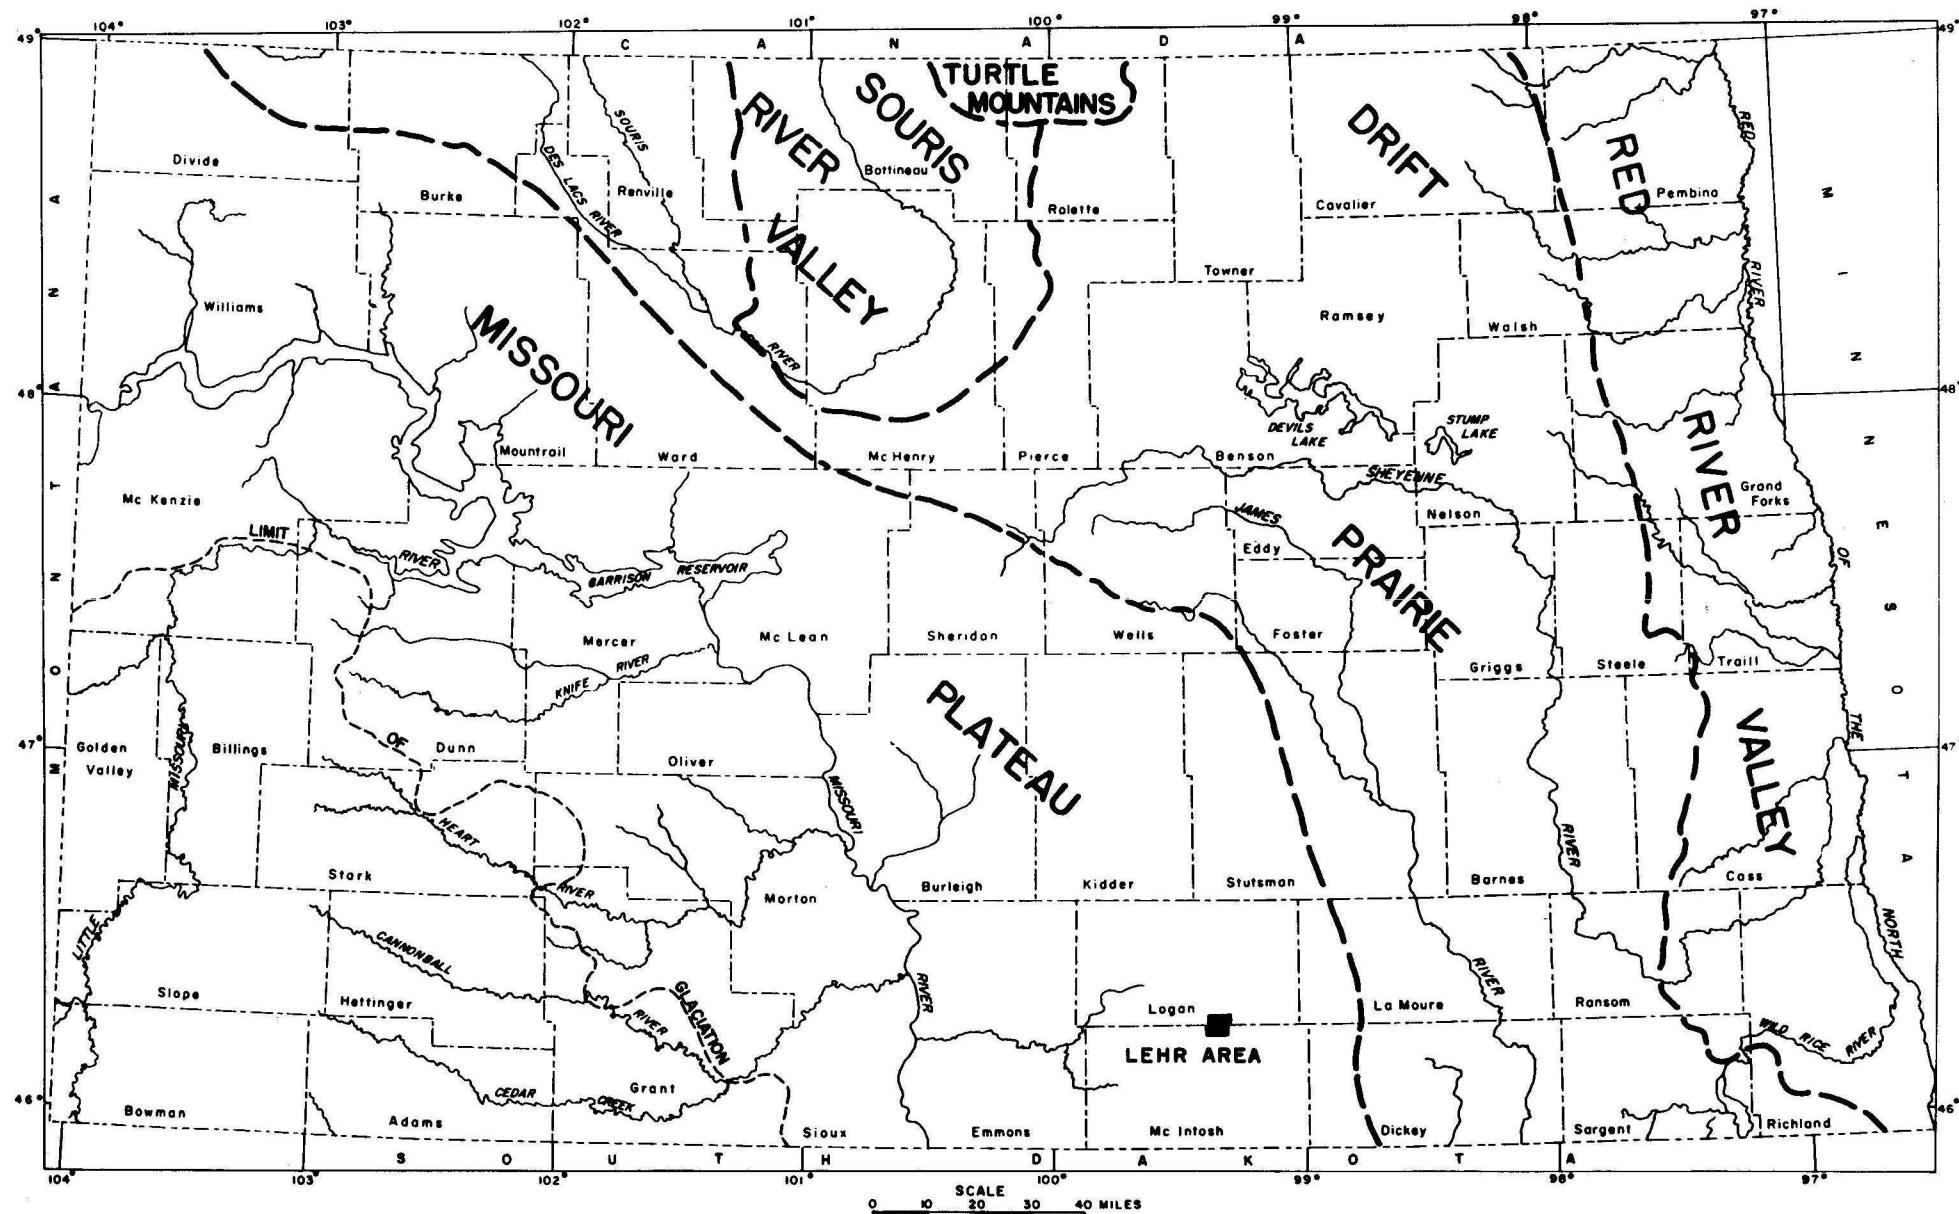

FIGURE I--PHYSIOGRAPHIC PROVINCES IN NORTH DAKOTA AND LOCATION OF THE LEHR AREA  
(MODIFIED FROM SIMPSON, 1929)

### Well-Numbering System

The well-numbering system used in this report, illustrated in figure 2, is based upon the location of the well in the federal system of rectangular surveys of the public lands. The first numeral denotes the township north of the base line, the second numeral denotes the range west of the fifth principal meridian, and the third numeral denotes the section in which the well is located. The letters a, b, c, and d designate respectively the northeast, northwest, southwest, and southeast quarter sections, quarter-quarter sections, and quarter-quarter-quarter sections (10-acre tracts). Consecutive terminal numerals are added if more than one well is shown in a 10-acre tract. Thus, well 132-69-5bad is in the SE<sup>1</sup><sub>4</sub>NE<sup>1</sup><sub>4</sub>NW<sup>1</sup><sub>4</sub> sec. 5, T. 132 N., R. 69 W.

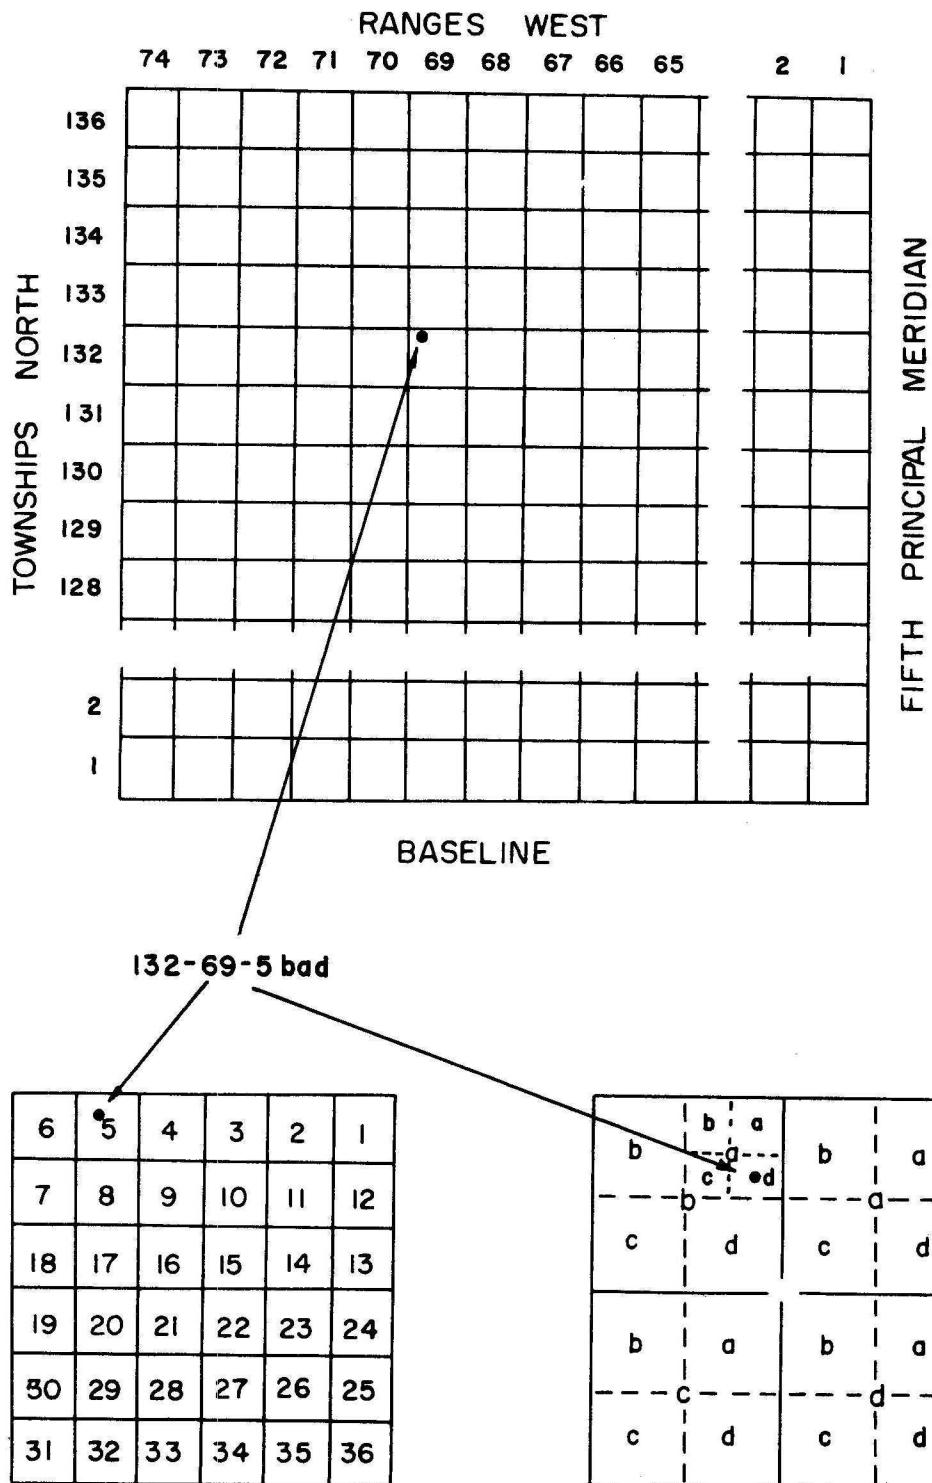

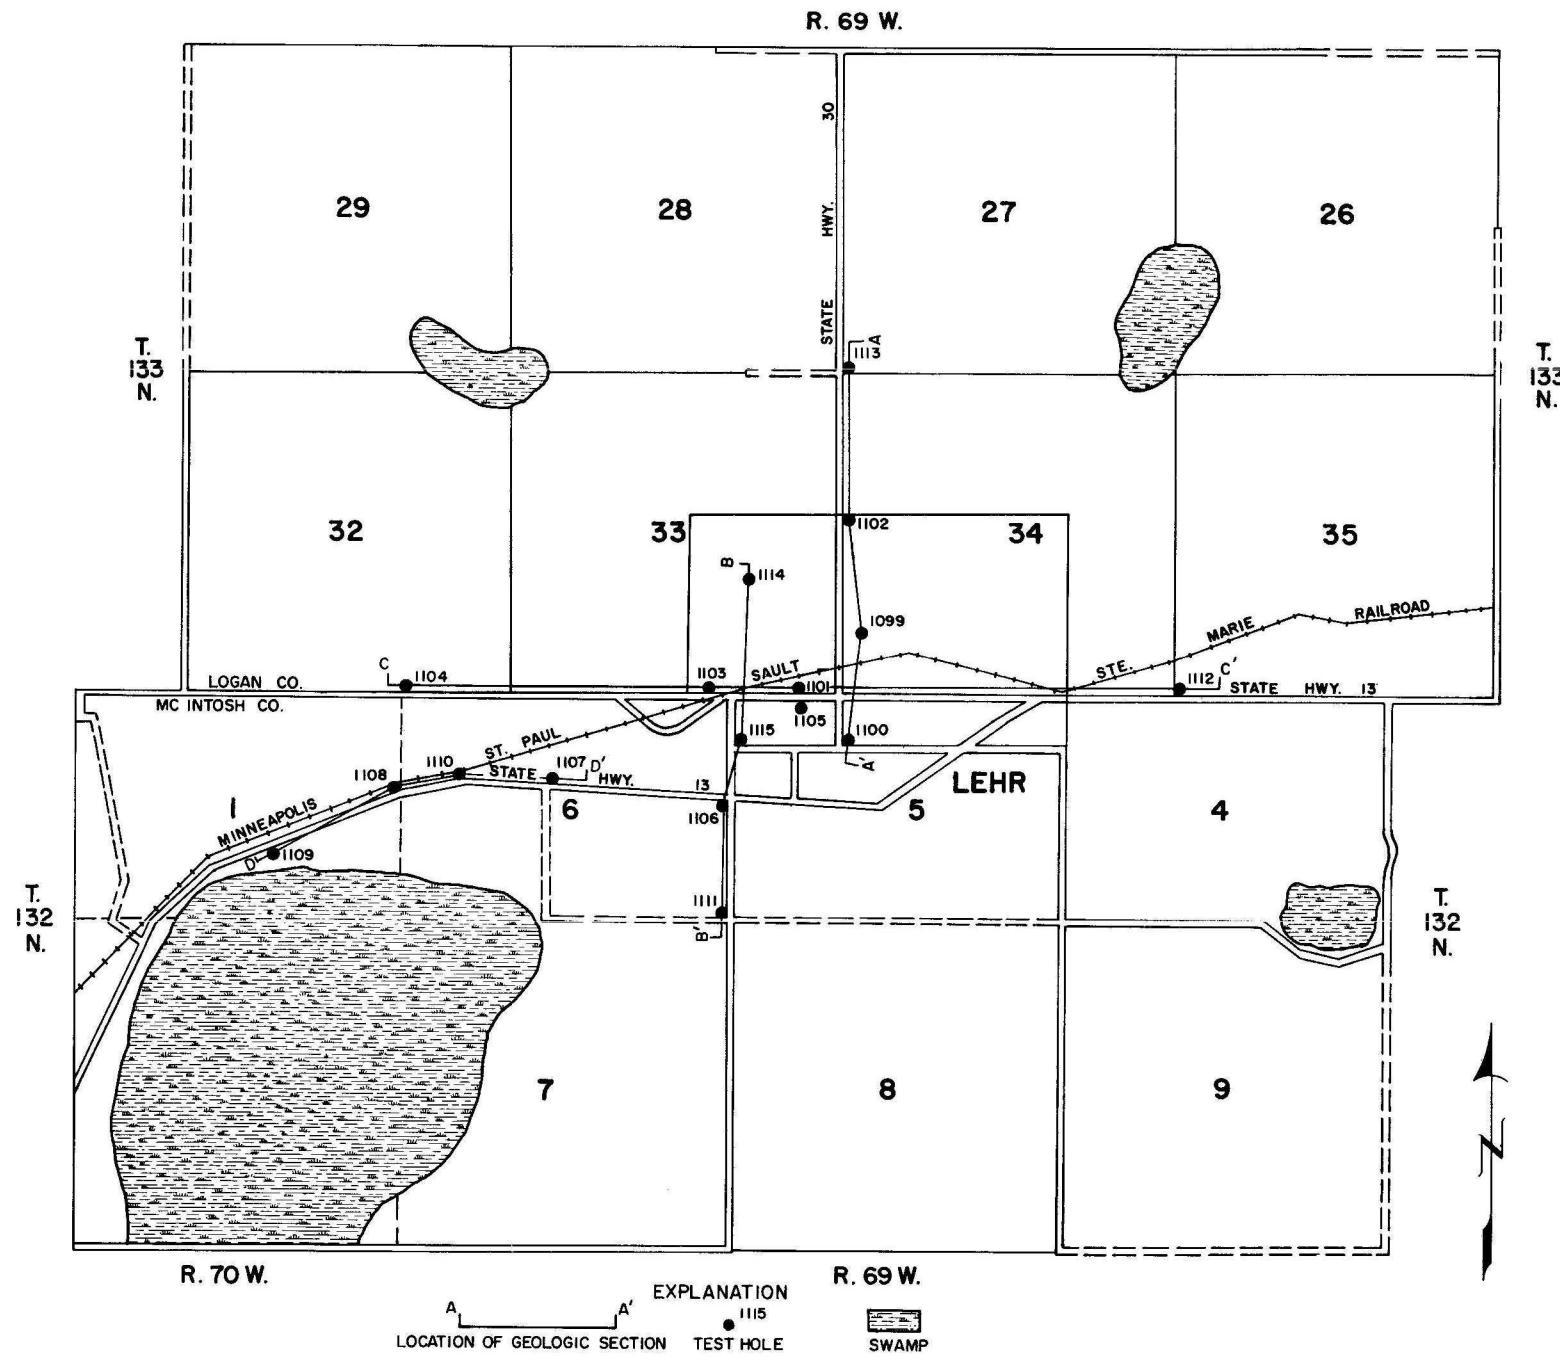

Figure 2 -- Sketch illustrating well-numbering system

### Geology and Ground Water

The surface of the Lehr area is covered by unconsolidated deposits of glacial drift consisting primarily of till. Ordinarily till is composed of a heterogeneous mixture of rock material ranging in size from clay to boulders. Because openings or pore spaces between the larger particles of the till are generally filled with fine particles, the unit has low permeability and does not yield water to wells readily. However, isolated deposits or lenses of stratified sand and gravel occur at places within the till, and where these are saturated, they provide a relatively productive source of ground water.

Sand and gravel deposits underlie till or fine-grained glacial material in a shallow valley or depression 1 mile west of Lehr. The sand and gravel deposits, which are saturated with ground water under artesian pressure, are surrounded by relatively impervious till. They were probably laid down by glacial melt water and they may extend continuously along the length of the valley as well as across it; if so, they constitute a relatively extensive aquifer. The sand and gravel deposits penetrated by test holes 1107, 1108, 1109, and 1110 are probably interconnected and delineate at least part of this aquifer. (See figs. 3 and 4, sec. D-D'.) The aquifer has 18 feet of medium to coarse saturated sand and 9 feet of fine to coarse saturated gravel in test hole 1108 (table 2), from which water flowed at the land surface. Probably the aquifer contains sufficient ground water for a municipal supply adequate to meet Lehr's present (1961) needs. Additional test drilling and one or more aquifer tests would be necessary to determine the hydrologic characteristics and to find the boundaries of the deposits.

An analysis of the chemical quality of ground water from test hole 1108 (132-70-lada) is given in table 1. The sampled water is very hard and has an iron content that is substantially higher than generally accepted standards. From studies of the State, however, in neighboring areas, it is apparent that the quality of ground water from glacial drift ranges considerably in character.

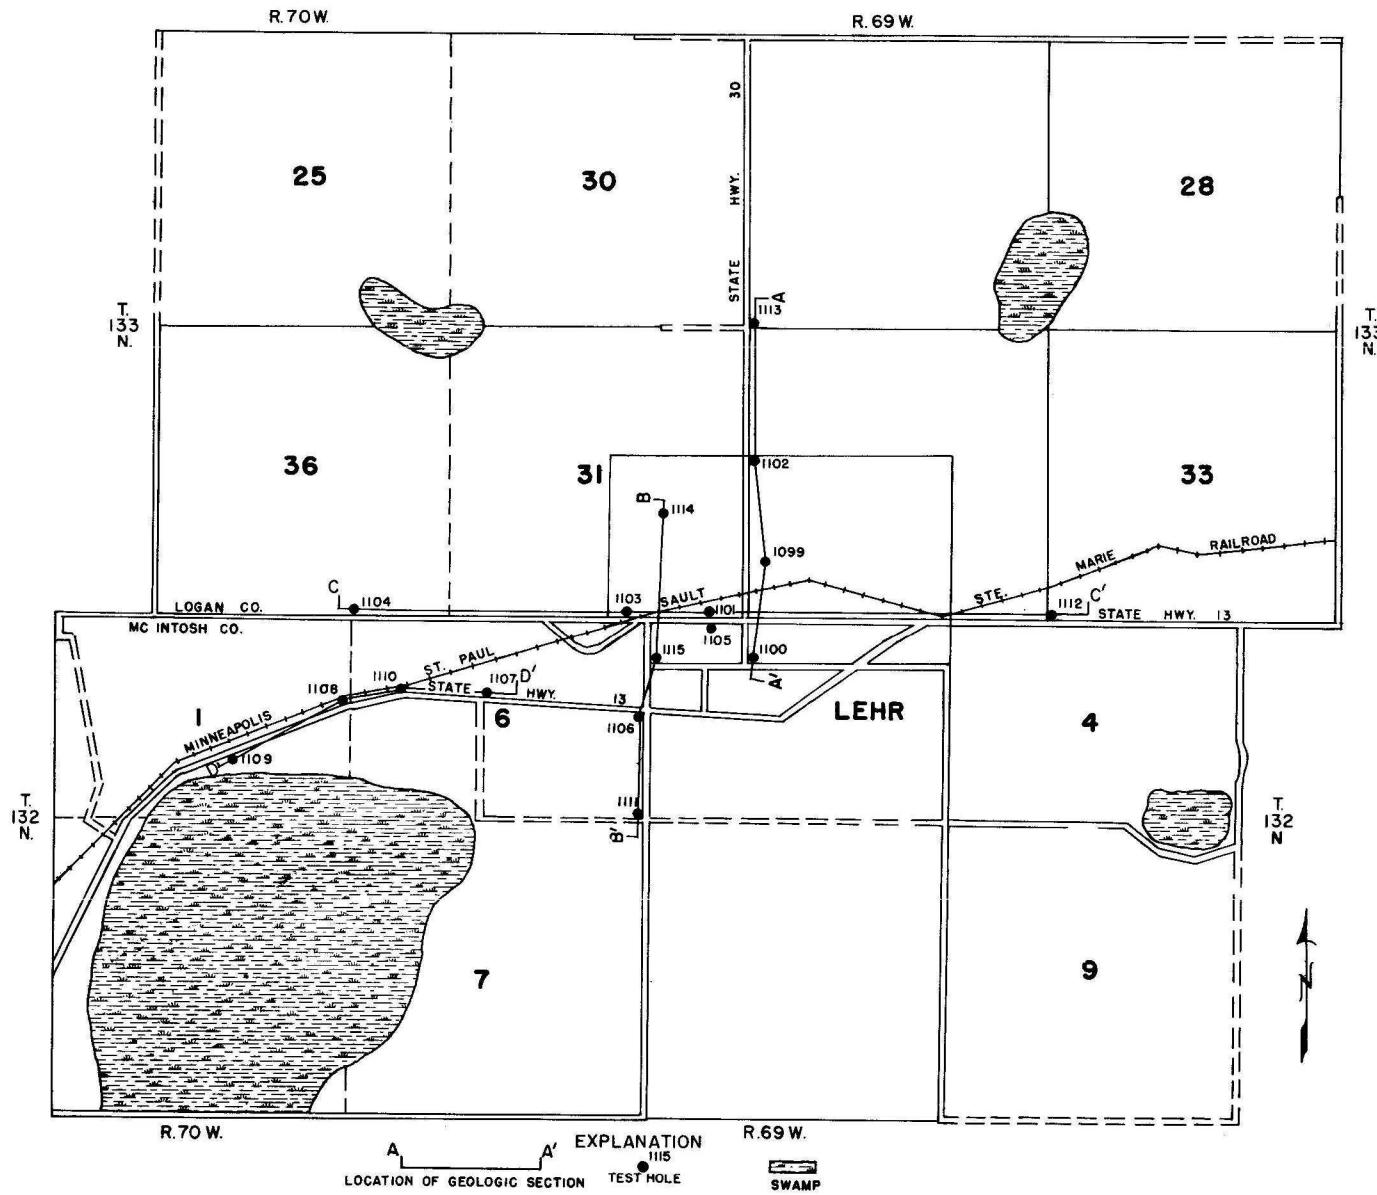

FIGURE 3 --MAP SHOWING LOCATION OF TEST HOLES IN THE LEHR AREA

The Pierre Shale of Late Cretaceous age underlies the glacial drift in the entire area. In the test holes penetrating bedrock, the depth to the Pierre ranges from 55 to 442 feet and averages 153 feet. The Pierre is not a source of water to wells or springs in the area.

#### Conclusion

Water-yielding deposits in the Lehr area occur as isolated sand and gravel lenses within the till. Ordinarily these lenses are not connected and, therefore, are not sources of large ground-water supplies. In a valley west of Lehr, fine-grained glacial deposits are underlain by what may be a relatively large saturated sand and gravel lens within the till; the aquifer in this lens may yield enough ground water to meet Lehr's present (1961) demands. For a more complete appraisal of the quantity and quality of ground water in the area, additional hydrologic and geologic data are needed.
